Usinage de l'aluminium

Gamme Aluminium

Métal léger, mais travail exigeant ?

Malgré le développement constant de nouveaux matériaux légers, l'aluminium reste très populaire — notamment dans les industries automobile et aérospatiale. Ses propriétés uniques nécessitent un savoir-faire spécialisé et des outils adaptés.

L'aluminium est généralement considéré comme facile à usiner, mais il présente des pièges : lors de l'usinage, il peut fondre sous l'effet de la chaleur générée. Cela obstrue l'espace à copeaux et empêche la formation de nouveaux copeaux. En conséquence, la surface de la pièce peut devenir inutilisable et, dans le pire des cas, l'outil peut se briser.

Pour atteindre une qualité d'usinage élevée, des outils spéciaux sont nécessaires et les paramètres de coupe doivent être maîtrisés. Conscients des besoins de nos clients, nous avons consacré beaucoup de temps au développement de nos nouveaux outils dédiés à l'aluminium.

Conseils et astuces d'usinage

Lors du fraisage de l'aluminium, voici les principaux paramètres à maîtriser :

- **Matière** : aluminium corroyé de classe 1, 2 ou 3
- **Outil** : nombre de dents, revêtement et autres paramètres
- **Avance et vitesse de coupe**
- **Lubrifiants** : oui ou non ?
- **Technique de fraisage** : fraisage en opposition / en avalant, fraisage hélicoïdal ou trochoïdal

Matière

L'aluminium se divise en trois classes de matériaux :

Classe 1 : Aluminium à faible résistance. Cela entraîne souvent l'adhérence ou le beurrage des copeaux, et donc la formation d'arêtes rapportées.

Classe 2 : Aluminium à résistance accrue. L'effet d'usure est moindre et la formation d'arêtes rapportées est réduite.

Classe 3 : Inclut les matériaux à décolletage libre. Ces matériaux produisent des copeaux courts et ne sont pas sujets à la formation d'arêtes rapportées.

Outil de coupe

La stabilité et la robustesse sont essentielles pour la fraise. Les fraises stables vibrent moins et produisent de meilleures surfaces tout en évitant les ruptures. Des arêtes de coupe polies engendrent une surface lisse et les copeaux sont évacués de manière optimale.

L'espace à copeaux est également crucial. En particulier lors de l'usinage d'alliages d'aluminium, il est indispensable d'évacuer les copeaux de la zone de travail aussi efficacement que possible. Il faut trouver le meilleur équilibre entre la charge sur l'arête de coupe et l'évacuation des copeaux. Les fraises bas de gamme sont déconseillées : elles s'usent plus vite et ont une durée de vie nettement plus courte.

Avance et vitesse de coupe

Des vitesses de coupe élevées produisent des surfaces plus lisses, mais augmentent l'usure. Il est important de respecter les recommandations du fabricant. Selon l'alliage, la vitesse recommandée est comprise entre 100 et 500 m/min, pour une avance entre 0,02 et 0,10 mm/Z.

Caractéristiques

| Caractéristiques techniques | |
|---|--|
| Matière | Carbure monobloc |
| Type de revêtement | 22304 22306 22308 22310 22312 22314 : MnAlu 22305 22307 22309 22311 22313 22315 : MnDLC |
| Type de queue | avec HA ou HB |
| Diamètre | de 2,0 à 20,0 mm |
| Géométrie | Pas inégal / torsion inégale, arête de coupe polie, avec et sans arrosage interne (AI), avec et sans brise-copeaux |
| Profondeur de passe a_p | jusqu'à 2×D |
| Largeur de coupe a_e | 0,5×D |
| Applications | Particulièrement adapté aux productions en série |

Lubrifiant : oui ou non ?

Un refroidissement adéquat est indispensable. Une surchauffe de la zone d'usinage peut provoquer des variations thermiques dans le matériau, nuisant à la durée de vie de l'outil ou à la précision dimensionnelle.

Technique de fraisage

La technique de fraisage a un impact direct sur la qualité de la pièce finie. Il convient de choisir la technique la mieux adaptée à votre application.

Aptitude

| Classe de matière | Adapté |
